

General

Should	Example	Shouldn't	Explain
The name should be English nouns			
Use only singular nouns	<code>inventory</code> , <code>shelf</code> , <code>octopus</code>	<code>inventories</code> , <code>shelves</code> , <code>octopuses</code> , <code>octopi</code> , <code>octopodes</code>	Save time thinking
Use only <code>lower_case</code>	<code>customer</code>	<code>Customer</code>	
Use only underscores <code>_</code> to concatenate words	<code>first_name</code>	<code>FirstName</code> , <code>firstName</code> , <code>"First Name"</code>	It's easier to read, there's no need to think when there will be uppercase letters, whenever there is an underline
Names are self-explanatory, avoid abbreviations, avoid data types instead of names	<code>middle_name</code> , <code>blog .content</code> , <code>amt</code>	<code>mid_nm</code> , <code>blog .text</code> , <code>amount</code>	Easy to understand
Avoid using SQL keywords	<code>display_order</code> , <code>updated_at</code>	<code>order</code> , <code>date</code>	A syntax error may occur if not enqueue
Short names, should not be longer than 64 characters			

Table

Should	Example	Shouldn't	Explain
Set prefix for related tables	<code>catalog_category</code> , <code>catalog_product</code>		Finding tables is easier
Add suffix <code>_tmp</code> to temporary tables for calculation but not delete	<code>catalog_product_price_tmp</code>		To distinguish it from the junk table can be deleted
Add <code>tmp_</code> prefix to temporary tables	<code>tmp_im_calculating</code>		

Column

Column

Should	Example	Shouldn't	Explain
Avoid adding unnecessary prefixes	<code>product.name</code>	<code>product.product_name</code>	The table name specifies the context
Add the <code>is_</code> prefix to YES / NO fields	<code>is_active</code> , <code>is_delivered</code> <code>is_free_shipping</code>	<code>active</code> , <code>delivered</code> , <code>free_shipping</code>	Looking at the field, we know there are only 2 values
Should save the time to change the data with each record	<code>created_at</code> , <code>updated_at</code> , <code>deleted_at</code>		Tracking data integrity
No naming containing data types	<code>return_code</code>	<code>int_return_code</code>	Data types can change: date => timestamp, int => bigint

Primary Key

Should	Example	Shouldn't	Explain
Only use PK as <code>id</code>	<code>table.id</code>	<code>table</code> <code>.table_id</code>	Easy to remember, reduce effort when renaming the table later
Each table should have 1 PK, in addition to the other UNIQUE KEY	PRIMARY KEY (id), UNIQUE KEY idx_unique (key1,key2)		Working with records faster
The default PK should be used as type Integer, Auto-increment			

Foreign Keys

Should	Example	Explain
The FK name is a combination of the field name and the table name it refers to	<code>person_id</code> is the FK of the table and the <code>person.id</code> field	Easy to understand
The Cascading Update option can be used, but Cascading Delete should be avoided		Reducing the risk of accidentally deleting a record in the main table makes all relevant data disappear

Indexes

Should	Example	Explain
Add the <code>idx_</code> prefix at the beginning	<code>idx_created_at</code>	Easy to remember, especially when ALTER TABLE without using the GUI Tool

Stored Procedure

Should	Example	Explain
Add the <code>sp_</code> prefix at the beginning, according to the <code>sp_table_action</code>	<code>sp_information_update</code>	Easy to remember

Trigger

Should	Example	Explain
Add the <code>tg_</code> prefix at the beginning, according to the <code>tg_table_action</code> structure	<code>tg_information_after_edit</code>	Easy to remember

View

Should	Example	Explain
Add the <code>vw_</code> prefix at the beginning, according to the <code>vw_table_information</code> structure	<code>vw_information_after_edit</code>	Easy to remember
